

Q1. What are the primary design goals of JavaScript?

A: JavaScript was designed with specific priorities around performance, safety, or developer productivity depending on its domain. These goals shape its syntax, type system, and standard library choices.

Q2. How does JavaScript handle type checking: static or dynamic?

A: JavaScript uses its type system to catch errors at compile time (static) or at runtime (dynamic). This affects refactoring safety, tooling support, and the kinds of bugs that reach production.

Q3. How does JavaScript manage memory?

A: JavaScript uses one of three approaches: manual allocation/deallocation, a garbage collector that periodically reclaims unreachable objects, or automatic reference counting. Each has different latency and throughput tradeoffs.

Q4. What is JavaScript's concurrency model?

A: JavaScript supports concurrency through threads, coroutines, async/await, or an actor model. The choice determines how I/O-bound and CPU-bound workloads are scaled and how shared state is safely accessed.

Q5. How are packages and dependencies managed in JavaScript?

A: JavaScript uses a package manager and a manifest file to declare dependencies and version constraints. A lock file pins exact versions to ensure reproducible builds across environments.

Q6. How does JavaScript implement object-oriented or functional programming?

A: JavaScript supports classes and inheritance for OOP, or first-class functions and immutability for FP, or both. Many modern JavaScript programs blend both paradigms depending on the problem.

Q7. How does JavaScript handle errors?

A: JavaScript surfaces errors via exceptions, Result/Either types, or error return values. The choice impacts whether errors are checked at compile time and how calling code is structured.

Q8. What testing tools are commonly used in JavaScript?

A: JavaScript has a standard or widely adopted test runner and assertion library. Tests are typically organized into unit, integration, and end-to-end layers with coverage reporting built in or via plugins.

Q9. What makes JavaScript well-suited for its target domain?

A: JavaScript excels in its domain due to a combination of performance characteristics, ecosystem maturity, language ergonomics, and community support that makes common tasks simple.

Q10. What are common performance pitfalls in JavaScript?

A: Typical performance issues in JavaScript include excessive allocations, blocking the main thread or event loop, $O(n^2)$ data structures, and missing caching. Profiling and benchmarking tools are available to diagnose them.
